b) Build a convolutional neural network either from scratch or existing modelsScreenshots of new convolutional neural network from scratch:

```

1 model = Sequential([
2     Conv2D(filters=32,kernel_size=(3,3),activation='relu', padding='same', input_shape=(224,224,3)),
3     MaxPool2D(pool_size=(2,2),strides=2),
4     Conv2D(filters=64,kernel_size=(3,3),activation='relu',padding='same'),
5     MaxPool2D(pool_size=(2,2),strides=2),
6     Conv2D(filters=128,kernel_size=(3,3),activation='relu',padding='same'),
7     MaxPool2D(pool_size=(2,2),strides=2),
8     Flatten(),
9     Dense(units=5,activation='softmax')])
10 model.summary()

```

Model: "sequential"

Layer (type)	Output Shape	Param #
conv2d (Conv2D)	(None, 224, 224, 32)	896
max_pooling2d (MaxPooling2D)	(None, 112, 112, 32)	0
conv2d_1 (Conv2D)	(None, 112, 112, 64)	18496
max_pooling2d_1 (MaxPooling2D)	(None, 56, 56, 64)	0
conv2d_2 (Conv2D)	(None, 56, 56, 128)	73856
max_pooling2d_2 (MaxPooling2D)	(None, 28, 28, 128)	0
flatten (Flatten)	(None, 100352)	0
dense (Dense)	(None, 5)	501765

=====  
 Total params: 595,013  
 Trainable params: 595,013  
 Non-trainable params: 0

3 pairs of Conv2D with each having 32,64 and 128 output filters using ReLU as activation function & MaxPool2D had been layered on top of each other followed by a flatten and dense layer of 5 units using "softmax" as activation function. ReLU function returns all negative values as 0 and maximum positive number is taken in for consideration. With its linearity feature for positive numbers, it allows scaling of the CNN network without having exponential growth in the computation power needed. Softmax function is most suitable for multi-classification model as it returns the probabilities of each class & target class that has the highest probability.

### Screenshots of training of model:

**Screenshots of evaluation of the model prediction:**

- Using our model to predict the 5 categories

5

```

1 y_pred = np.argmax(output_layer, axis=-1)
2 print(y_pred)
3 #type(y_pred)

```

```

[0 0 0 4 0 0 0 0 4 0 0 0 4 4 2 1 1 0 0 0 0 0 1 0 1 1 1 1 3 4 4 1 1 4 2 1 2
 1 0 1 2 1 2 2 2 3 2 2 3 3 1 0 2 4 2 2 2 2 4 4 3 3 3 3 1 3 3 2 0 3 3 3 3
 2 3 4 2 2 2 4 1 4 0 4 1 4 4 4 4 2 0 0 3 4 4 4 4]

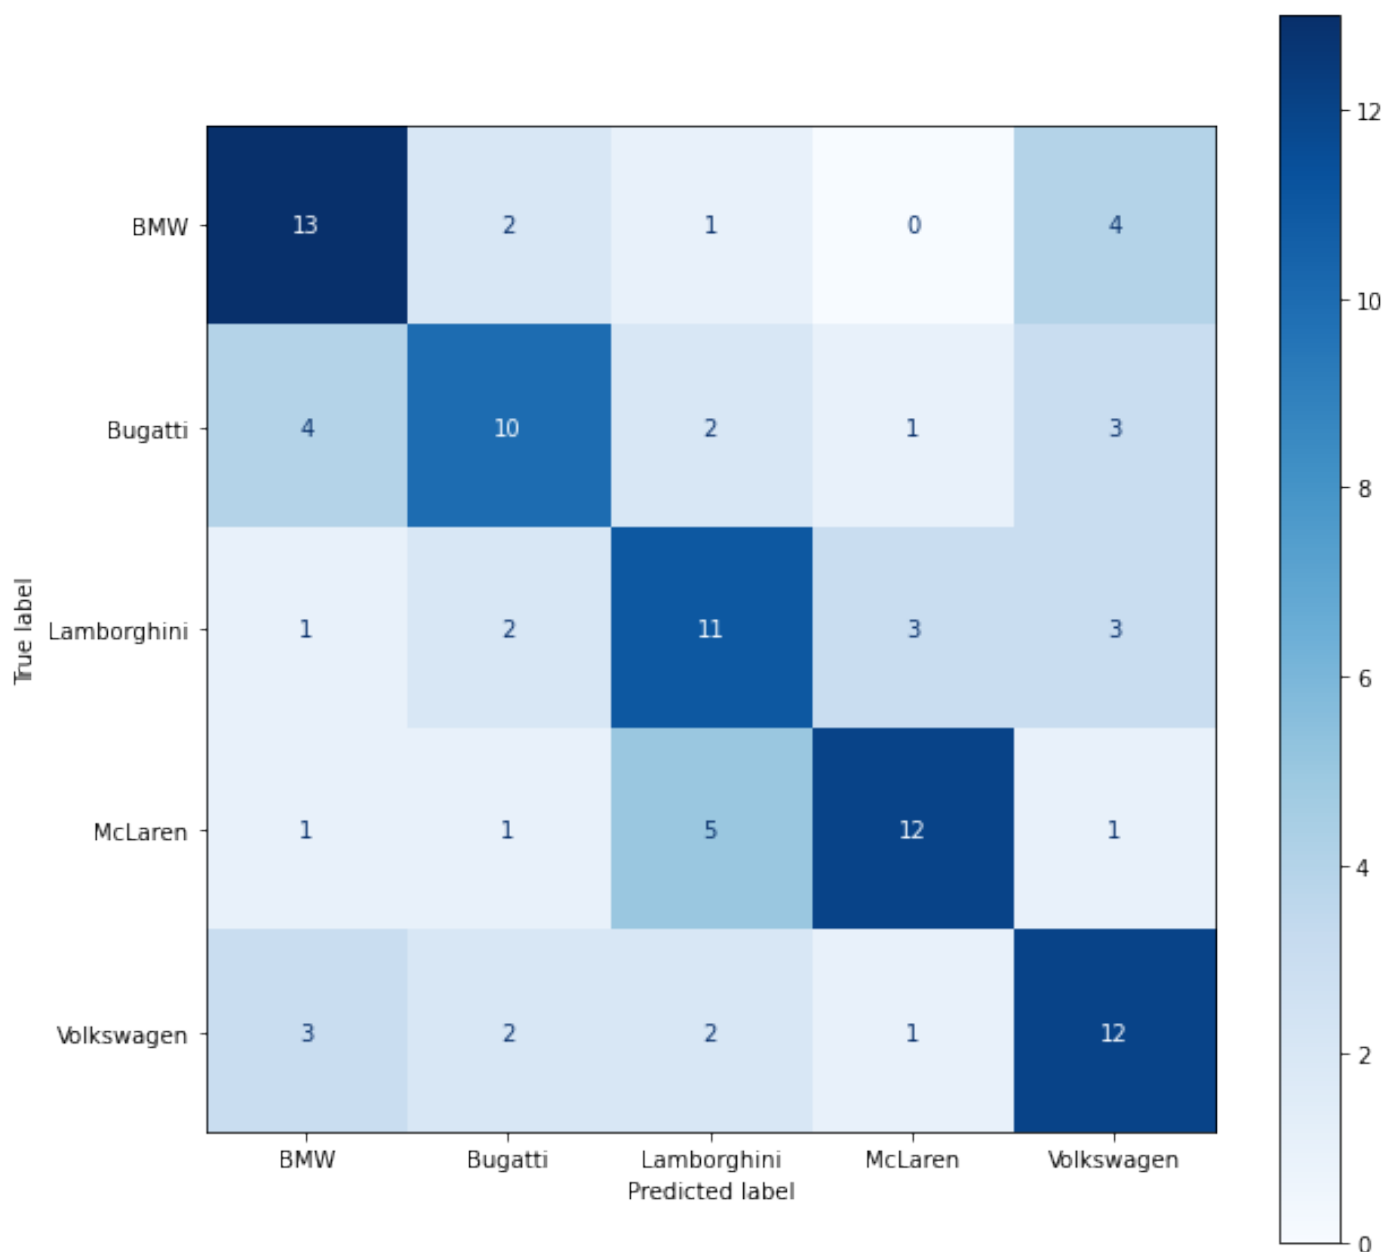

```

## - Plotting of Confusion Matrix

```

1 cm = confusion_matrix(y_test, y_pred)
2
3 disp = ConfusionMatrixDisplay(confusion_matrix=cm, display_labels=['BMW', 'Bugatti', 'Lamborghini', 'McLaren', 'Volkswagen'])
4 fig, ax = plt.subplots(figsize=(10,10))
5 disp.plot(ax=ax, cmap=plt.cm.Blues)

```

- Prediction Accuracy of 58%

```
[ ] 1 Accuracy = accuracy_score(y_test, y_pred)
    2 print(Accuracy)
```

0.58

- d) Based on error analysis and online materials, suggest a proper direction that can lead to better performance of your model in your presentation document

### 1) Error Analysis

- Screenshot of getting F<sub>1</sub>-Score

Code is from [1]:

```
1 from sklearn.metrics import classification_report
2 print('\nClassification Report\n')
3 print(classification_report(y_test, y_pred, target_names=['BMW', 'Bugatti', 'Lamborghini', 'McLaren', 'Volkswagen']))
```

Classification Report

	precision	recall	f1-score	support
BMW	0.59	0.65	0.62	20
Bugatti	0.59	0.50	0.54	20
Lamborghini	0.52	0.55	0.54	20
McLaren	0.71	0.60	0.65	20
Volkswagen	0.52	0.60	0.56	20
accuracy			0.58	100
macro avg	0.59	0.58	0.58	100
weighted avg	0.59	0.58	0.58	100

Macro and Weighted average F<sub>1</sub> score is 0.58 as all the 5 classes have 20 images each with an accuracy of 58% of the test data set that was stated in part c. Among the classes, McLaren seems to have the highest F<sub>1</sub>-score which shows that the model is better at identifying McLaren thus indicating certain level of biasness. Since the average F<sub>1</sub> score is not near 1 and low accuracy overall, the model is not being generalised well enough.

- Screenshots of graph of Model Accuracy and Model Loss

```
1 print(history.history.keys())
2 # summarize history for accuracy
3 plt.plot(history.history['accuracy'])
4 plt.plot(history.history['val_accuracy'])
5 plt.title('Model Accuracy')
6 plt.ylabel('accuracy')
7 plt.xlabel('epoch')
8 plt.legend(['Train', 'Validation'], loc='upper left')
9 plt.show()
10 # summarize history for loss
11 plt.plot(history.history['loss'])
12 plt.plot(history.history['val_loss'])
13 plt.title('Model Loss')
14 plt.ylabel('loss')
15 plt.xlabel('epoch')
16 plt.legend(['Train', 'Validation'], loc='upper left')
17 plt.show()
```

- Graph of Model Loss

Based on the accuracy graph above, the accuracy of the model has hit a plateau for both training and validation data set. In addition, training set accuracy is also higher than validations set, this would mean the model is overfitting. As for the loss graph, there is no significant reduction after reaching 1 epoch on the validation data. Thus, further increasing of the epoch no. is not recommended for these settings of the model.

## 2) Online materials

The model would require more generalization as there is an overfitting situation currently. Regularization can prevent overfitting thus improving generalization. One of the ways is through data augmentation with the given fixed set of data, thus the model will not see the same picture twice [2],[3],[4]. Data augmentation is a preprocessing technique where there is cropping, flipping, zooming, shearing, translation and etc of the original images [3].

Images taken from [5],[6],[7]

Example of Shearing:

Example of Cropping:

Example of Flipping:

Example of Translation:

Name: Lim Junwei Darien

Matriculation No.: U1921811F

There are also other data augmentation methods, such as CutMix and MixUp that can generate high-quality inter-class images. CutMix randomly crops portions of one image and overlay onto another image whereas MixUp interpolates pixel values between 2 images, it has a result of a faded layer onto another image [8].

Images taken from [9]

Example of CutMix:

Example of MixUp:

However, either CutMix or MixUp is usually implemented in most machine learning models not at the same time [8].

e) Implement the new direction suggested in d) and demonstrate better evaluation metrics in your prediction outcome

1) Implementing several changes based on data augmentation to improve the metrics which are:

1.1 Changing ImageDataGenerator()

The implementation below was reference from [4].

```
1 IDG=ImageDataGenerator(rescale=1./255,rotation_range=200, horizontal_flip=True,vertical_flip=True, fill_mode='reflect',shear_range=0.2,zoom_range=0.1)
2 train_batches = IDG.flow_from_directory(directory=train_path, target_size=(224,224), classes=['BMW', 'Bugatti', 'Lamborghini','McLaren','Volkswagen'], batch_size=10)
3
4 valid_batches = IDG.flow_from_directory(directory=valid_path, target_size=(224,224), classes=['BMW', 'Bugatti', 'Lamborghini','McLaren','Volkswagen'], batch_size=10)
5
6 test_batches = IDG.flow_from_directory(directory=test_path, target_size=(224,224), classes=['BMW', 'Bugatti', 'Lamborghini','McLaren','Volkswagen'],
7                                     batch_size=10,shuffle=False)
8 #There are 3 channels which are RGB, thus input shape is (224,224,3)
```

Found 400 images belonging to 5 classes.  
Found 100 images belonging to 5 classes.  
Found 100 images belonging to 5 classes.

ImageDataGenerator() have included for all training, validation and test batches :

- Rescaling of 1/255 factor, this is to reduce the RGB coefficients between 0 and 1 for easy processing by the model.
- Random rotation of 200°
- Horizontal & vertical flipping
- Random shearing of 0.2 in intensity and random zooming in of of the original
- Random zooming of 0.1 ([1-zoom\_range, 1+zoom\_range], where zoom\_range is 0.1)

These are the results:

```
[ ] 1 plotImages(imgs)
    2 print(labels)
```

WARNING:matplotlib.image:Clipping input data to the valid range for imshow with RGB data ([0..1] for floats or [0..255] for integers).  
WARNING:matplotlib.image:Clipping input data to the valid range for imshow with RGB data ([0..1] for floats or [0..255] for integers).  
WARNING:matplotlib.image:Clipping input data to the valid range for imshow with RGB data ([0..1] for floats or [0..255] for integers).  
WARNING:matplotlib.image:Clipping input data to the valid range for imshow with RGB data ([0..1] for floats or [0..255] for integers).  
WARNING:matplotlib.image:Clipping input data to the valid range for imshow with RGB data ([0..1] for floats or [0..255] for integers).  
WARNING:matplotlib.image:Clipping input data to the valid range for imshow with RGB data ([0..1] for floats or [0..255] for integers).  
WARNING:matplotlib.image:Clipping input data to the valid range for imshow with RGB data ([0..1] for floats or [0..255] for integers).  
WARNING:matplotlib.image:Clipping input data to the valid range for imshow with RGB data ([0..1] for floats or [0..255] for integers).  
WARNING:matplotlib.image:Clipping input data to the valid range for imshow with RGB data ([0..1] for floats or [0..255] for integers).

It shows that the images have successfully been augmented.

## 1.2 Adding CutMix to our training set after ImageDataGenerator()

The code was reference from [10] and implemented which is shown below:

```

1 pip install cutmix-keras

Looking in indexes: https://pypi.org/simple, https://us-python.pkg.dev/colab-wheels/public/simple/
Collecting cutmix-keras
  Downloading cutmix-keras-1.0.0-py3-none-any.whl (3.6 kB)
Installing collected packages: cutmix-keras
Successfully installed cutmix-keras-1.0.0

[10] 1 from cutmix_keras import CutMixImageDataGenerator

1 train_generator1=IDG\
2 .flow_from_directory(directory=train_path,target_size=(224,224),classes=['BMW', 'Bugatti', 'Lamborghini','McLaren','Volkswagen'],batch_size=10,shuffle=True)
3 train_generator2=IDG\
4 .flow_from_directory(directory=train_path,target_size=(224,224),classes=['BMW', 'Bugatti', 'Lamborghini','McLaren','Volkswagen'],batch_size=10,shuffle=True)
5 train_generator = CutMixImageDataGenerator(
6     generator1=train_generator1,
7     generator2=train_generator2,
8     img_size=(224), #only accept one argument, it will set the width and height to be the same
9     batch_size=10)
10 B=train_generator.samples

Found 400 images belonging to 5 classes.
Found 400 images belonging to 5 classes.

```

These are the results:

It shows that the images have successfully been cut & mix

## 1.3 Adding MixUp to our training set after ImageDataGenerator() as an another alternative method to compare with CutMix performance

The source code was reference from [11] and changes (red boxes) were made to fit our classification problem before being implemented which is shown below:

```

1 #Source code taken from https://github.com/Tony607/keras_mixup_generator
2 #Edits were made to fit our classification problem
3 import numpy as np
4
5 class MixupImageDataGenerator():
6     def __init__(self, generator, directory, batch_size, img_height, img_width, classes, alpha=0.2, subset=None): #Classes were added
7         """Constructor for mixup image data generator.
8         Arguments:
9             generator {object} -- An instance of Keras ImageDataGenerator.
10            directory {str} -- Image directory.
11            batch_size {int} -- Batch size.
12            img_height {int} -- Image height in pixels.
13            img_width {int} -- Image width in pixels.
14        Keyword Arguments:
15            alpha {float} -- Mixup beta distribution alpha parameter. (default: {0.2})
16            subset {str} -- 'training' or 'validation' if validation_split is specified in
17            'generator' (ImageDataGenerator).(default: {None})
18        """
19
20        self.batch_index = 0
21        self.batch_size = batch_size
22        self.alpha = alpha
23
24        # First iterator yielding tuples of (x, y)
25        self.generator1 = generator.flow_from_directory(directory,
26            target_size=(
27                img_height, img_width),
28                classes=classes, #Edits were made here
29                batch_size=batch_size,
30                shuffle=True,
31                subset=subset)

```

```

33 # Second iterator yielding tuples of (x, y)
34 self.generator2 = generator.flow_from_directory(directory,
35                                               target_size=(
36                                                 img_height, img_width),
37                                               classes=classes, #Edits were made here
38                                               batch_size=batch_size,
39                                               shuffle=True,
40                                               subset=subset)
41

```

```

100 def __iter__(self):
101     while True:
102         yield next(self)

```

These are the results:

```

1 plotImages(img)
2 print(label)

```

It shows that the images have successfully been mixup with a faded overlay of original images.

## 1.4 Adding data augmentation as a layer into our model

Reference was made from [12] for the below implementation:

```
1 data_augmentation = Sequential([
2     RandomFlip("horizontal_and_vertical",input_shape=(224,224,3)),
3     RandomRotation(factor=0.5),
4     RandomTranslation(height_factor=(0.1),
5         width_factor=(0.1),
6         fill_mode='wrap',
7         interpolation='bilinear',
8         seed=None,))]
9 data_augmentation.summary()
```

3 different augmentations have been added as preprocessing layers, which allow further data augmentation whenever the training dataset passes through the model for every iteration.

Adding of the data augmentation layer into our current model:

```
[18] 1 model1 = Sequential(
2     [data_augmentation,
3     Conv2D(filters=32,kernel_size=(3,3),activation='relu', padding='same', input_shape=(224,224,3)),
4     MaxPool2D(pool_size=(2,2),strides=2),
5     Conv2D(filters=64,kernel_size=(3,3),activation='relu',padding='same'),
6     MaxPool2D(pool_size=(2,2),strides=2),
7     Conv2D(filters=128,kernel_size=(3,3),activation='relu',padding='same'),
8     MaxPool2D(pool_size=(2,2),strides=2),
9     Flatten(),
10    Dense(units=5,activation='softmax')]
11 )
12 model1.summary()
```

This is the result:

Layer (type)	Output Shape	Param #
sequential (Sequential)	(None, 224, 224, 3)	0
conv2d (Conv2D)	(None, 224, 224, 32)	896
max_pooling2d (MaxPooling2D)	(None, 112, 112, 32)	0
conv2d_1 (Conv2D)	(None, 112, 112, 64)	18496
max_pooling2d_1 (MaxPooling2D)	(None, 56, 56, 64)	0
conv2d_2 (Conv2D)	(None, 56, 56, 128)	73856
max_pooling2d_2 (MaxPooling2D)	(None, 28, 28, 128)	0
flatten (Flatten)	(None, 100352)	0
dense (Dense)	(None, 5)	501765

=====  
 Total params: 595,013  
 Trainable params: 595,013  
 Non-trainable params: 0

## 2) Demonstration of better evaluation metrics in prediction outcome

Mixup & Cutmix are compared to choose the better method that gives us higher prediction accuracy.

### 2.1 Mixup Implementation

#### 2.1.1 Model Accuracy

The model was trained in 2 different epochs

Graph 1 at 150 Epoch

Graph 2 at 300 Epoch

The accuracy graphs show increasing trends for both training and validation set with minimal difference between them for graph 1 which suggested that the model is a good fit, thus this motivates the continual increasing of epoch no. to get higher accuracy. However, at graph 2 with 300 epoch the accuracy between the training and validation set starts to diverge at about 200 epochs with training set exceeding the validation set this indicates the starting of an overfitting model. Therefore, epochs no. below 200 but above 150 can provide a good fit for our future prediction.

#### 2.1.2 Model Loss

Graph 1 at 150 Epoch

Graph 2 at 300 Epoch

The graph 1 show that there is a decreasing trend happening for both training and validation set losses, which prompted the increase of epoch no. as well which coincides with the accuracy graphs 1. Graph 2 with 300 epochs shows that there is a divergence at about 200 epochs with the validation set loss starts to increase while training set loss continue to decrease, which are signs of overfitting.

Graph of prediction accuracy with epoch no & hours for Mixup.

The graph above overall shows that there is an increasing trend of the prediction accuracy when there is an increase of epochs no. which indicates that increasing epochs no. increases the model prediction accuracy. The incremental change of the prediction accuracy is significant of 7% between epochs 150 & 300 with twice the time spent training at 150 epochs. However, the maximum of epoch would be 300 as further increase of the epoch would result in overfitting of the model and decrease the prediction accuracy, therefore the highest accuracy for this model is 79% at 300 epochs.

## 2.2 Cutmix Implementation

An additional step is required to extract the steps required per epoch from Cutmix generator shown in part e,1.2 as the function is not able to return the steps required per epoch for the fitting of the model later on.

```
1 model1.compile(optimizer=Adam(learning_rate=0.0001), loss='categorical_crossentropy', metrics=['accuracy'])  
2 A=train_generator.get_steps_per_epoch()  
3 print(A)
```

40

The model was trained in 4 different epochs, 150,300,500,800:

### 2.2.1 Model Accuracy:

Graph 1 at 150 Epoch

Graph 2 at 300 Epoch

Graph 3 at 500 Epoch

Graph 4 at 800 Epoch

The accuracy graphs show increasing trends for both training and validation set with minimal difference between them for graph 1,2,3 with increasing epoch which suggested that the model is a good fit, thus this motivates the continual increasing of epoch no. to get higher accuracy. However, at graph 4 with 800 epoch the accuracy between the training and validation set starts to diverge with training set exceeding the validation set this indicates the starting of an overfitting model. Therefore, 800 epoch is the limit of this model to have a good fit for our future prediction.

2.2.2 Model Loss

Graph 1 at 150 Epoch

Graph 2 at 300 Epoch

Graph 3 at 500 Epoch

Graph 4 at 800 Epoch

The graphs of 1,2,3 show that there is a decreasing trend happening for both training and validation set losses, which prompted the increasing of epoch no. as well which coincides with the accuracy graphs 1,2,3. Graph 4 at 800 epoch shows that there is a convergence happening when the validation set loss starts to increase while training set loss continue to decrease, which are starting signs of overfitting. Nevertheless, this indicates that the model is stable and is a good fit at 800 epochs as well. In addition, the reason why the validation set loss is consistently below the training set is because that our validation set mostly is made up of “easy” images to predict, as Cutmix was only done on the training set. This also shows that Cutmix brings in higher complexity into the training set than Mixup for this case. This also recommends that validation set should also have comparable complexity with the training set for future improvements to give a more accurate insights of the performance of the model.

2.2.3 Prediction Accuracy:

Graph of prediction accuracy with epoch no &amp; hours for cutmix.

The graph above overall shows that there is an increasing trend of the prediction accuracy when there is an increase of epochs no. which indicates that increasing epochs no. increases the model prediction accuracy. However, the incremental change of the prediction accuracy is not very significant after 300 epochs which might not worth the time taken to increase the prediction accuracy by a small number in this case is 2%; 500 epochs took 2.5 hours & 800 epochs took 4 hours. Nevertheless, the final run at 800 epochs gave us the highest prediction accuracy of 84%.

2.3 Comparing between Cutmix & Mixup Prediction Accuracy

	Mixup @300 Epochs	Cutmix @ 800 Epoch
Highest Prediction Accuracy (%)	79	84

Table of Highest Prediction Accuracy between Mixup and Cutmix

The table shows that Cutmix overall gives us the highest prediction accuracy, thus it will be implemented to our current model.

## 2.4 Overall Comparison between before and after new implementations (data augmentation)

**Confusion matrix**

Confusion matrix 1 before implementation of data augmentation

Confusion matrix 2 after implementation of data augmentation

Comparing both confusion matrixes, confusion matrix 2 has more correctly predicted classes than confusion matrix 1 that is indicated by the increase no. of darker shades boxes and its numbers have about 17 correctly predicted for each class.

### Prediction accuracy

	Before implementation of data augmentation	After implementation of data augmentation
Prediction Accuracy (%)	58	84
Increase of Prediction Accuracy (%)	26	
Percentage Change (%)	48	

Table of Prediction Accuracy before and after implementation of data augmentation

The table shows that there is an increase of 26% prediction accuracy after the implementation of data augmentation that amounts to 48% percentage change.

### F<sub>1</sub> score

Classification Report						
	Precision		Recall		F <sub>1</sub> Score	
	Before	After	Before	After	Before	After
BMW	0.59	0.85	0.65	0.85	0.62	0.85
Bugatti	0.59	0.81	0.50	0.85	0.54	0.83
Lamborghini	0.52	0.74	0.55	0.85	0.54	0.79
McLaren	0.71	0.89	0.60	0.80	0.65	0.84
Volkswagen	0.52	0.94	0.60	0.85	0.56	0.89
<b><u>Average</u></b>	0.59	0.85	0.58	0.84	0.58	0.84
<b><u>Average Increase</u></b>	0.26					

Table of Classification Report before & after implementation of data augmentation

The new implementation improved the model ability to correctly predict and reduce false negative in all the classes which is shown in the table with an average of 0.26 increase in precision, recall after implementation of data augmentation. This resulted in an increase average of 0.26 of the F<sub>1</sub> score also, with the new F<sub>1</sub> score being 0.84. There is still certain level of biasness, with Volkswagen and Bugatti having 0.79 and 0.89 respectively of the F<sub>1</sub> score.

### Conclusion

Therefore, the implementation of data augmentation to regularize the model is effective with providing better generalization as shown by the improved confusion matrix, increased of prediction accuracy and F<sub>1</sub> score.
